### Comparing A Multiple Regression Model

Comparing a Multiple Regression Model Across Groups We might want to know whether a particular set of predictors leads to a multiple regression model that works equally effectively for two (or more) different groups (populations, treatments, cultures, social-temporal changes, etc.). Here's an example...

Linear regression is one of the most common techniques of regression analysis. Multiple regression is a broader class of regressions that encompasses linear and nonlinear regressions with multiple...

### Understanding Linear Regression vs. Multiple Regression

When comparing regression models that use the same dependent variable and the same estimation period, the standard error of the regression goes down as adjusted R-squared goes up. Hence, the model with the highest adjusted R-squared will have the lowest standard error of the regression, and you can just as well use adjusted R-squared as a criterion for ranking them.

SPSS fitted 5 regression models by adding one predictor at the time. The model summary table shows some statistics for each model. The adjusted r-square column shows that it increases from 0.351 to 0.427 by adding a third predictor.

I have another model with predictor variable  $x_1$ . My understanding is that when you have multiple predictors, you use adjusted R-squared, but with only one predictor, you use  $x_1$ . So when I am trying to compare the goodness of fit of the two different models I mentioned above, should I be comparing R-squared or adjusted R-squared?

You could well base a model comparison on residuals, for instance residual sum square RSS is a function of residuals. But not in the way you are doing it, a t.test comparing residuals. The t test will compare the mean of the residuals, but that will always be zero (least squares) or approximately zero (more general maximum likelihood), so the t test will never reject, so is not useful for ...
